TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE

MODEL WITH AN ASPECT RATIO 4 TRIANGULAR WING AND AN

ALL-MOVABLE HORIZONTAL TAIL - HIGH-LIFT

DEVICES AND LATERAL CONTROLS

By Ralph W. Franks

## SUMMARY

Tests have been made of a triangular-wing-airplane model equipped with high-lift devices and lateral and directional controls. The model consisted of an aspect ratio 4 triangular wing in combination with a fuselage of fineness ratio 12.5; a thin, triangular, vertical tail with a constant-chord rudder; and a thin, unswept, all-movable horizontal tail. The wing had an NACA 0005 modified section and was equipped with partial-span, constant-chord, slotted inboard flaps, and plain, constant-chord, outboard flaps.

Three lateral controls were tested; namely, the inboard flaps, the outboard flaps, and the all-movable horizontal tail. The high-lift devices were the outboard flaps and the inboard flaps. Tests were made with the wing-fuselage-vertical-tail configuration in addition to the tests of the complete model. The Reynolds number, based on the wing mean aerodynamic chord, was approximately 10.9 million and the Mach number was approximately 0.13.

## INTRODUCTION

The low-speed aerodynamic characteristics of an airplane model with an aspect ratio 4 triangular wing and an all-movable horizontal tail have been under investigation in the Ames 40- by 80-foot wind tunnel. The longitudinal aerodynamic characteristics of the model at zero sideslip have been reported in reference 1; included therein were data covering the effect of horizontal-tail aspect ratio and vertical location. The

~~CONFIDENTIAL~~~~CONFIDENTIAL~~  
SECURITY INFORMATION

results of the tests of reference 1 indicated that the horizontal tail having the greater aspect ratio (4.4) located in the extended wing-chord plane gave the best stability and the lowest drag; therefore, this tail configuration was used in the present investigation.

Presented herein are the results of tests of the model with high-lift devices, and lateral and directional controls. The high-lift devices included slotted inboard flaps and plain outboard flaps. Three lateral controls were tested; namely, the inboard flaps, the outboard flaps, and the all-movable horizontal tail. In addition, a rudder of constant chord was tested as a directional control device. The data herein are presented without analysis to expedite publication.

#### NOTATION

The coefficients and symbols used in this report are defined as follows and as shown in figure 1, wherein all force and moment coefficients, angles, and control deflections are shown as positive. All control deflections are measured in a plane perpendicular to the control hinge line.

- $\alpha$  angle of attack of the wing-chord plane with reference to free stream, degrees
- $b$  wing span, feet
- $b_i$  inboard flap span (total movable), feet
- $b_o$  outboard flap span (total movable), feet
- $b_t$  horizontal-tail span, feet
- $\beta$  angle of sideslip of the model center line with reference to free stream, degrees
- $c$  wing chord, measured parallel to wing center line, feet
- $\bar{c}$  mean aerodynamic chord of wing, measured parallel to wing center line  $\left( \frac{\int_0^{b/2} c^2 dy}{\int_0^{b/2} c dy} \right)$ , feet
- $C_D$  drag coefficient  $\left( \frac{\text{drag}}{qS} \right)$

- $C_l$  rolling-moment coefficient  $\left( \frac{\text{rolling moment}}{qSb} \right)$
- $C_L$  lift coefficient  $\left( \frac{\text{lift}}{qS} \right)$
- $C_m$  pitching-moment coefficient  $\left( \frac{\text{pitching moment}}{qS\bar{c}} \right)$
- $C_n$  yawing-moment coefficient  $\left( \frac{\text{yawing moment}}{qSb} \right)$
- $C_Y$  side-force coefficient  $\left( \frac{\text{side force}}{qS} \right)$
- $\delta_i$  average deflection of the inboard flaps, degrees
- $\delta_l$  difference in deflection between any pair of control surfaces used as lateral controls, positive when left-hand surface has the more positive deflection, degrees
- $\delta_o$  average deflection of the outboard flaps
- $\delta_r$  rudder deflection (positive when trailing edge moves to left), degrees
- $\Delta$  prefix denoting an increment
- $\epsilon_{av}$  average effective downwash angle, degrees
- $i_t$  average horizontal-tail incidence relative to the wing-chord plane, degrees
- $l_t$  distance from moment center of model to pivot line of horizontal tail, feet
- $\frac{L}{D}$  lift-drag ratio
- $p$  rate of rolling, radians per second
- $\frac{pb}{2V}$  wing-tip helix angle, radians
- $q$  free-stream dynamic pressure, pounds per square foot
- $S$  wing area, square feet

$S_i$  inboard flap area (total movable), square feet  
 $S_o$  outboard flap area (total movable), square feet  
 $S_r$  rudder area (total movable), square feet  
 $S_t$  horizontal-tail area (total movable), square feet  
 $V$  free-stream velocity, feet per second  
 $W$  airplane weight, pounds  
 $x$  longitudinal coordinate parallel to model center line, feet  
 $y$  lateral coordinate perpendicular to plane of symmetry, feet  
 $z$  vertical coordinate perpendicular to wing-chord plane, feet

$$C_{l_\beta} \left( \frac{\partial C_l}{\partial \beta} \right)$$

$$C_{l_p} \left[ \frac{\partial C_l}{\partial (pb/2V)} \right]$$

$$C_{n_\beta} \left( \frac{\partial C_n}{\partial \beta} \right)$$

$$C_{Y_\beta} \left( \frac{\partial C_Y}{\partial \beta} \right)$$

$i$  inboard flaps  
 $o$  outboard flaps  
 $t$  horizontal tail

#### MODEL

The model used in the present investigation was that described in reference 1, with the addition of a rudder and inboard and outboard

trailing-edge flaps. The model was equipped with the horizontal tail of aspect ratio 4.4 described in reference 1. Dimensional data of the model are presented in figure 2 and table I. A photograph of the model as mounted in the wind tunnel is shown in figure 3.

The rudder and the outboard flaps were of constant chord and had plain radius noses. The inboard flaps were of constant chord and of the slotted type. Details of the inboard flaps and the path of travel of the inboard flaps during deflection are shown in figure 4.

### TESTS AND PROCEDURE

The configurations tested are listed in table II. The flaps and the horizontal tail were tested as lateral-control surfaces by deflecting these surfaces antisymmetrically, the deflections being superposed on initial symmetrical settings. During the investigation simultaneous deflections of the inboard and outboard flaps were used to simulate the effect of full-span flaps. Tests were also made with the rudder deflected to ascertain rudder effectiveness and possible control interaction between rudder and horizontal tail when the tail was being used as a lateral control.

The data were corrected for wind-tunnel-wall effects using the theory described in reference 2. These corrections were:

$$\Delta\alpha = 0.67 C_L$$

$$\Delta C_D = 0.012 C_L^2$$

$$\Delta C_m = -0.014 C_L \text{ (tail-on configurations only)}$$

The data were also corrected for support-strut interference. No corrections were applied to the data for possible deflection of the control surfaces due to aerodynamic loads since they were believed to be negligible. The accuracy of setting of all control-surface deflections was within  $\pm 0.2^\circ$ . The average Reynolds number of the tests was 10.9 million based on the mean aerodynamic chord of the wing. The dynamic pressure was approximately 25 pounds per square foot and the Mach number was approximately 0.13.

### RESULTS

The basic experimental data obtained are presented in figures 5 to 13, which are indexed in table II. The moment data in all figures are

referred to a moment center located at 40.8 percent of the mean aerodynamic chord of the wing. This is the moment center for which a static margin,  $-(dC_m/dC_L)_{C_L=0}$ , of 0.06 would be obtained when the trailing-edge flaps and the horizontal tail are undeflected.

The effects of inboard-flap deflection and horizontal-tail incidence on the pitching-moment characteristics are shown in figure 14. The variations of the average effective downwash angle with angle of attack at the position of the horizontal tail were determined from the pitching-moment data obtained during the test and are presented in figure 15. These values were determined by making the assumption that for any given tail incidence, the intersection of the tail-on and the tail-off pitching-moment curves indicates the lift-coefficient value at which the pitching moment due to the tail is zero; hence, the average angle of flow across the tail is zero. In order to obtain points of intersection for tail incidences other than those tested, a linear variation of  $dC_m/di_t$  was assumed.

In figure 16 the increments of lift coefficient obtained experimentally on the wing-fuselage-vertical-tail configuration at  $0^\circ$  angle of attack with  $40^\circ$  inboard flap deflection and various outboard flap deflections are plotted against values obtained through application of the theory of reference 3.

The trimmed lift and drag characteristics for the model in level flight, based on a 30 pounds per square foot wing loading, are shown in figure 17. The dashed portion of the lift curve indicates a region of longitudinal instability with inboard flaps deflected. This destabilizing effect, shown in the pitching-moment curves of figure 14, is believed due to the destabilizing variation of downwash with angle of attack through this region, as indicated in figure 15 by the increasing slope of the downwash curve.

The effectiveness of the flaps and the horizontal tail as lateral controls is shown in figures 18 to 21. The increments of rolling-moment coefficient were obtained from figures 5, 6, 9, and 10 and were based on a differential lateral-control deflection of  $20^\circ$ . For each lateral control tested, the effectiveness as predicted by the theory of reference 4 has been plotted.

The variations of  $pb/2V$  with  $C_L$  for each lateral control is shown in figure 22. In computing these values, use was made of values of rolling-moment coefficients obtained experimentally with a  $20^\circ$  differential lateral-control surface deflection, a rudder deflection of  $0^\circ$ , and the model held at  $0^\circ$  sideslip. The values of  $C_{l_p}$  were obtained from figure 13 of reference 5. It should be noted that the reason for

the rapid increase of  $p_b/2V$  at high lift coefficients is due to the decrease of the damping-in-roll parameter at the higher lift coefficients.

The rudder defectiveness, based on a  $10^\circ$  rudder deflection with inboard flaps deflected, is shown in figure 23 as well as the effect of the use of the horizontal tail as a lateral-control device on the rudder effectiveness.

The sideslip derivatives,  $C_{n\beta}$ ,  $C_{l\beta}$ , and  $C_{y\beta}$ , as measured near  $0^\circ$  of sideslip from the data plotted in figures 7 and 12, are presented in figure 24. Values are shown for the wing-fuselage-vertical-tail configuration and for the complete model with flap deflections of  $0^\circ$  and  $40^\circ$  in both cases.
